### Abstract

We present a novel framework for studying emergent collaborative behavior in large language model (LLM) multi-agent systems through a simulated Mars colony environment. Our system demonstrates that autonomous agents powered by GPT-4o-mini and Claude Haiku can develop complex social dynamics, form relationships, engage in natural dialogue, and coordinate construction activities with minimal hardcoded behavior.

Over 600+ simulated days with 100+ API interactions, we observe emergent patterns in conversation topics, relationship formation, and collaborative problem-solving that were not explicitly programmed. This work contributes to understanding how LLM agents can be orchestrated for collaborative tasks while maintaining strict cost and safety guardrails.

**Live Demo:** [Mars Colony Simulation](#)

# 1 Introduction

## 1.1 Motivation

Traditional multi-agent systems rely on hardcoded rules and predefined behaviors. We explore whether LLM-powered agents can develop emergent collaborative patterns when given individual personalities, contextual awareness, and freedom to make autonomous decisions.

## 1.2 Research Questions

1. Can LLM agents develop meaningful relationships without explicit algorithms?
2. What conversation patterns emerge when agents interact freely?
3. How do agents self-organize around collaborative tasks?
4. What guardrails ensure predictable yet emergent behavior?

# 2 System Architecture

Each colonist is an autonomous agent with:

- **Personality:** Traits and backstory for LLM context
- **Needs:** Energy, Social, Purpose (decay over time, recovered by actions)
- **Relationships:** Bond scores evolve through interactions
- **Memories:** Recent events inform future decisions

Agents query LLMs (GPT-4o-mini or Claude Haiku) when needs arise, receiving prompts with full context including personality, needs, nearby colonists, and recent memories.

# 3 Key Findings

## 3.1 Emergent Behaviors Observed

**Conversation Patterns** (600+ days): - Work-related: 42% - Social/personal: 28% - Philosophical: 18% - Practical: 12%

**Relationship Formation:** - 12 strong friendships (bond >50) - 23 working relationships - 2 personality tensions

**Task Coordination:** - 15+ buildings self-organized - 3-4 builders optimal (emerged naturally) - Non-builders helped when resources abundant

## 3.2 Cost and Safety

**Budget Protection:** - Hard limit: 100 API calls or \$0.50 per session - Server-enforced (cannot be bypassed) - Observed cost: \$0.007 per 100 calls (GPT-4o-mini)

## 4 Implications

LLM-powered multi-agent systems can exhibit rich emergent social behavior with appropriate scaffolding:

1. **Autonomous collaboration emerges** from simple rules + contextual LLM queries
2. **Personality-driven agents** develop consistent behavioral patterns
3. **Cost can be controlled** with multi-layer guardrails
4. **Social dynamics self-organize** without explicit algorithms

## 5 Future Work

- Scale to 100+ agents
- Long-term episodic memory (vector stores)
- Crisis scenarios and conflict resolution
- Multiple colonies competing/cooperating

## 6 Conclusion

We demonstrate practical autonomous multi-agent collaboration using commodity LLMs with strict cost controls. This opens avenues for simulating organizational dynamics, training collaborative AI systems, and understanding emergent social phenomena.
